## hypermaps

A **hypermap** can be represented by a pair of permutations  $(\sigma, \alpha)$  on  $[n] := \{1, 2, \dots, n\}$  that generate a transitive subgroup of the symmetric group  $\mathfrak{S}_n$ .

# hypermaps

A **hypermap** can be represented by a pair of permutations  $(\sigma, \alpha)$  on  $[n] := \{1, 2, \dots, n\}$  that generate a transitive subgroup of the symmetric group  $\mathfrak{S}_n$ .

$\sigma = (1)(2, 3)(4, 5, 6)$       (counterclockwise)      – vertices  
 $\alpha = (1, 2, 4)(3, 6)(5)$       (clockwise)      – hyperedges  
 $\alpha^{-1}\sigma = (1, 4, 5, 3)(2, 6)$       – face

## genus of a hypermap

The **genus** of the hypermap  $(\sigma, \alpha)$  is the nonnegative integer  $g_{\sigma, \alpha}$  defined by the equation

$$n + 2 - 2g_{\sigma, \alpha} = z(\sigma) + z(\alpha) + z(\alpha^{-1}\sigma),$$

where  $z(\sigma)$  is the number of cycles of  $\sigma$ .

## genus of a hypermap

The **genus** of the hypermap  $(\sigma, \alpha)$  is the nonnegative integer  $g_{\sigma, \alpha}$  defined by the equation

$$n + 2 - 2g_{\sigma, \alpha} = z(\sigma) + z(\alpha) + z(\alpha^{-1}\sigma),$$

where  $z(\sigma)$  is the number of cycles of  $\sigma$ .

	permutations	$z$
$\sigma$	$(1)(2, 3)(4, 5, 6)$	3
$\alpha$	$(1, 2, 4)(3, 6)(5)$	3
$\alpha^{-1}\sigma$	$(1, 4, 5, 3)(2, 6)$	2

$$g_{\sigma, \alpha} = \frac{1}{2} (6 + 2 - 3 - 3 - 2) = 0.$$

## hypermonopoles

A special case, called the **hypermonopole**, is a hypermap  $(\sigma, \alpha)$  where  $\sigma$  is the  $n$ -cycle  $\zeta_n = (1, 2, \dots, n)$ .

The **genus**  $g_\alpha$  of a permutation  $\alpha$  is defined as the genus of the hypermonopole  $(\zeta_n, \alpha)$ , i.e.,

$$n + 1 - 2g_\alpha = z(\alpha) + z(\alpha^{-1}\zeta_n).$$

permutations		$z$
$\sigma = \zeta_7$	$(1, 2, 3, 4, 5, 6, 7)$	1
$\alpha$	$(1, 2, 7)(3)(4, 5, 6)$	3
$\alpha^{-1}\zeta_7$	$(1)(2, 3, 6)(4)(5)(7)$	5

$$g_\alpha = \frac{1}{2} (7 + 1 - 3 - 5) = 0.$$

Enumeration of genus zero permutations with restrictions

## noncrossing partitions

Two disjoint subsets  $B$  and  $B'$  of  $[n]$  are **crossing** if there exist  $a, b \in B$  and  $c, d \in B'$  such that  $a < c < b < d$ . Otherwise,  $B$  and  $B'$  are **noncrossing**.

## noncrossing partitions

Two disjoint subsets  $B$  and  $B'$  of  $[n]$  are **crossing** if there exist  $a, b \in B$  and  $c, d \in B'$  such that  $a < c < b < d$ . Otherwise,  $B$  and  $B'$  are **noncrossing**.

A **noncrossing partition** of  $[n]$  is a set partition of  $[n]$ , denoted by  $\{B_1, B_2, \dots, B_k\}$ , such that the *blocks*  $B_j$  are pairwise noncrossing.

## a characterization of genus zero perm.

### Theorem (Cori 1975)

*Let  $\alpha \in \mathfrak{S}_n$ . Then  $g_\alpha = 0$  if and only if the cycle decomposition of  $\sigma$  gives a noncrossing partition of  $[n]$ , and each cycle of  $\alpha$  is increasing.*

## a characterization of genus zero perm.

### Theorem (Cori 1975)

Let  $\alpha \in \mathfrak{S}_n$ . Then  $g_\alpha = 0$  if and only if the cycle decomposition of  $\sigma$  gives a noncrossing partition of  $[n]$ , and each cycle of  $\alpha$  is increasing.

For example,  $\alpha = 329467851 = (1, 3, 9)(5, 6, 7, 8)$  is associated with the following noncrossing partition.

## sign-balance for genus 0 permutations

Let  $\sigma = \sigma_1 \cdots \sigma_n \in \mathfrak{S}_n$ . The **inversion number** of  $\sigma$  is defined by

$$\text{inv}(\sigma) := \#\{(\sigma_i, \sigma_j) : \sigma_i > \sigma_j, 1 \leq i < j \leq n\}.$$

## sign-balance for genus 0 permutations

Let  $\sigma = \sigma_1 \cdots \sigma_n \in \mathfrak{S}_n$ . The **inversion number** of  $\sigma$  is defined by

$$\text{inv}(\sigma) := \#\{(\sigma_i, \sigma_j) : \sigma_i > \sigma_j, 1 \leq i < j \leq n\}.$$

Let  $\mathcal{G}_n \subset \mathfrak{S}_n$  be the subset consisting of the permutations of genus zero. We observe that

$$\sum_{\sigma \in \mathcal{G}_n} (-1)^{\text{inv}(\sigma)} = \begin{cases} 0 & n \text{ even} \\ C_{\lfloor \frac{n}{2} \rfloor} & n \text{ odd,} \end{cases}$$

where  $C_n = \frac{1}{n+1} \binom{2n}{n}$  is the  $n$ th Catalan number.

## LRMin-distribution for genus 0 permutations

Let  $\text{LRMin}(\sigma)$  denote the number of *left-to-right minima* of  $\sigma$ , i.e.,

$$\text{LRMin}(\sigma) := \#\{\sigma_i : \sigma_i > \sigma_j, 1 \leq i < j\}.$$

The distribution of genus zero permutations w.r.t LRMin:

$n$	$ \mathcal{G}_n $	1	2	3	4	5	6	7	8
1	1	1							
2	2	1	1						
3	5	2	2	1					
4	14	5	5	3	1				
5	42	14	14	9	4	1			
6	132	42	42	28	14	5	1		
7	429	132	132	90	48	20	6	1	

# signed LRMin-distribution for $\mathcal{G}_n$

The sign-balance of LRMin-distribution for  $\mathcal{G}_n$ :

$n$	1	2	3	4	5	6	7	8	9
2	1	-1							
3	0	0	-1						
4	-1	1	-1	1					
5	0	0	1	0	1				
6	2	-2	2	-2	1	-1			
7	0	0	-2	0	-2	0	-1		
8	-5	5	-5	5	-3	3	-1	1	
9	0	0	5	0	5	0	3	0	1

# a refined sign-balance result

## Theorem (Eu-Fu-Pan-Ting 2018)

For all  $n \geq 1$ , the following identities hold.

$$\textcircled{1} \quad \sum_{\sigma \in \mathcal{G}_{2n+1}} (-1)^{\text{inv}(\sigma)} q^{\text{LRMin}(\sigma)} = (-1)^n q \sum_{\sigma \in \mathcal{G}_n} q^{2 \cdot \text{LRMin}(\sigma)},$$

$$\textcircled{2} \quad \sum_{\sigma \in \mathcal{G}_{2n}} (-1)^{\text{inv}(\sigma)} q^{\text{LRMin}(\sigma)} = (-1)^n \left(1 - \frac{1}{q}\right) \sum_{\sigma \in \mathcal{G}_n} q^{2 \cdot \text{LRMin}(\sigma)},$$

## Dyck paths

Let  $\mathcal{D}_n$  denote the set of **Dyck paths** of length  $n$ , i.e., the lattice paths from  $(0, 0)$  to  $(n, n)$ , using  $(0, 1)$  step and  $(1, 0)$  step, that stays weakly above the line  $y = x$ .

For a Dyck path  $\pi \in \mathcal{D}_n$ , let

- $\text{area}(\pi)$  = the number of unit squares enclosed by  $\pi$  and the line  $y = x$ ,
- $\text{fpeak}(\pi)$  = the height of the first peak of  $\pi$ .

# Dyck paths

Let  $\mathcal{D}_n$  denote the set of **Dyck paths** of length  $n$ , i.e., the lattice paths from  $(0,0)$  to  $(n,n)$ , using  $(0,1)$  step and  $(1,0)$  step, that stays weakly above the line  $y = x$ .

For a Dyck path  $\pi \in \mathcal{D}_n$ , let

- $\text{area}(\pi)$  = the number of unit squares enclosed by  $\pi$  and the line  $y = x$ ,
- $\text{fpeak}(\pi)$  = the height of the first peak of  $\pi$ .

**Figure:** A Dyck path  $\pi$  with  $\text{area}(\pi) = 9$  and  $\text{fpeak}(\pi) = 3$ .

# a bijection between genus 0 permutations and Dyck paths

## Theorem (Stump 2013)

*There is a bijection  $\phi : \sigma \rightarrow \pi$  of  $\mathcal{G}_n$  onto  $\mathcal{D}_n$  such that*

- 1  $\text{area}(\pi) = \text{inv}(\sigma)$ ,
- 2  $\text{fpeak}(\pi) = \text{LRMin}(\sigma)$ .

# a bijection between genus 0 permutations and Dyck paths

## Theorem (Stump 2013)

There is a bijection  $\phi : \sigma \rightarrow \pi$  of  $\mathcal{G}_n$  onto  $\mathcal{D}_n$  such that

- 1  $area(\pi) = inv(\sigma)$ ,
- 2  $fpeak(\pi) = LRMin(\sigma)$ .

Figure: The corresponding Dyck path of  $\sigma = (1, 3, 9)(5, 6, 7, 8)$ .

## even/odd peaks and valleys on Dyck paths

A peak/valley at  $(i, j)$  is said to be **even** (**odd**, respectively) if  $i + j$  is even (odd, respectively).

Figure: The red peaks/valleys are even..

## a sign-reversing involution on Dyck paths

Establish an involution  $\gamma : \pi \rightarrow \pi'$  on  $\mathcal{D}_n$  by changing the last even peak (or valley) into a valley (or peak). Then

- $|\text{area}(\pi') - \text{area}(\pi)| = 1$ ,
- $\text{fpeak}(\pi') = \text{fpeak}(\pi)$ .

Figure: The map  $\gamma : \pi \rightarrow \pi'$ .

the fixed points of the map  $\gamma$

# the fixed points of the map $\gamma$

Let  $\text{ferr}(\pi)$  denote the number of unit squares above the Dyck path  $\pi$  within the  $n \times n$  square, i.e.,  $\text{area}(\pi) = \frac{n(n-1)}{2} - \text{ferr}(\pi)$ .

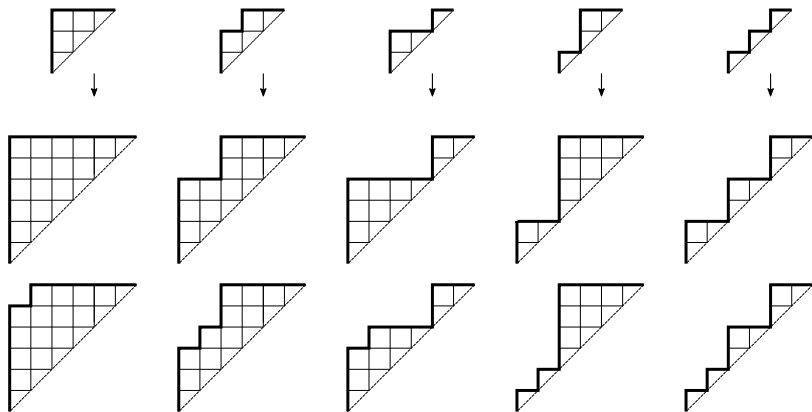

$$\gamma(\pi) = \pi \in \mathcal{D}_{2n+1} \rightarrow \text{ferr}(\pi) \text{ is even} \rightarrow \text{area}(\pi) \equiv n \pmod{2}$$

# the fixed points of the map $\gamma$ - odd case

$$\begin{aligned}
 \sum_{\sigma \in \mathcal{G}_7} (-1)^{\text{inv}(\sigma)} q^{\text{LRMin}(\sigma)} &= -q^7 - 2q^5 - 2q^3 \\
 &= -q \sum_{\sigma \in \mathcal{G}_3} q^{2 \cdot \text{LRMin}(\sigma)}.
 \end{aligned}$$

# the fixed points of the map $\gamma$ - even case

$$\sum_{\sigma \in \mathcal{G}_6} (-1)^{\text{inv}(\sigma)} q^{\text{LRMin}(\sigma)} = \left(-1 + \frac{1}{q}\right) \sum_{\sigma \in \mathcal{G}_3} q^{2 \cdot \text{LRMin}(\sigma)}.$$

Thanks for your attention.
